

The background of the slide features a collage of business and technology-related icons and images. On the left, there is a large, glowing database cylinder icon. In the center, a hand is shown drawing a lightbulb icon with a pen. To the right, there is a bar chart with an upward arrow. Below the bar chart, there is a network diagram with nodes and connecting lines. At the bottom, there are several circular icons, including a globe, a puzzle piece, and a circular arrow. The entire background has a warm, orange-brown color scheme.

# Intelligent Data Management with SQL Server

**Session: 1**

## ***RDBMS Concepts***

# Objectives

- Explain the concept of data and database
- Describe the approaches to data management
- Define a **Database Management System (DBMS)** and list its benefits
- Explain the different database models
- Define and explain **RDBMS**
- Describe **entities** and **tables** and list the characteristics of tables
- List the differences between a **DBMS** and an **RDBMS**

# Introduction

- Organizations often maintain large amounts of data, generated as a result of day-to-day operations.
- A database:
  - is an organized form of such data.
  - may consist of one or more related data items called records.
  - is a data collection to which different questions can be asked.
- For example,
  - 'What are phone numbers and addresses of five nearest post offices?' or
  - 'Do we have any books in our library that deal with health food?'

# Data and Database

When data is gathered and analyzed, it yields information.  
Intelligent interpretation of data yields information.

Information helps to foresee and plan events.

A database is an organized collection of data such that its contents can be easily accessed, managed, and updated.

## Example:

A **phone book** is a database consisting of names, addresses, and telephone numbers.

# Data Management

Data management deals with managing large amount of information, which involves:

- Storage of information
- Provision of mechanisms for the manipulation of information
- Providing safety of information stored under various circumstances

Two different approaches  
of managing data are:

File-based systems

Database systems

# File-based Systems

In a file-based system, data is stored in discrete files and a collection of such files is stored on a computer

Files of archived data were called tables

Rows in the table were called **records** and columns were called **fields**

Example:

First Name	Last Name	Address	Phone
Eric	David	<u><a href="mailto:ericd@eff.org">ericd@eff.org</a></u>	213-456-0987
Selena	Sol	<u><a href="mailto:selena@eff.org">selena@eff.org</a></u>	987-765-4321
Jordan	Lim	<u><a href="mailto:nadroj@otherdomain.com">nadroj@otherdomain.com</a></u>	222-3456-123

# Disadvantages of File-based Systems

Data redundancy and inconsistency

Unanticipated queries

Data isolation

Concurrent access anomalies

Security problems

Integrity problems

# Database Systems

Database Systems evolved in the late 1960s to address common issues in applications handling large volumes of data, which are also data intensive.

Databases are used to store data in an efficient and organized manner. A database allows quick and easy management of data

At any point of time, data can be retrieved from the database, added, and searched based on some criteria in these databases.

Data storage can be achieved even using simple manual files.

Data stored in this form is not permanent. Records in such manual files can only be maintained for a few months or few years.

# Advantages of Database Systems

Amount of redundancy in the stored data can be reduced

No more inconsistencies in data

Stored data can be shared

Standards can be set and followed

Data Integrity can be maintained

Security of data can be implemented

# Database Management System (DBMS) 1-3

A DBMS is a collection of related records and a set of programs that access and manipulate these records and enables the user to enter, store, and manage data.

In a centralized database system, the database is stored in the central location which everybody can have access from their machine.

A database is a collection of interrelated data and a DBMS is a set of programs used to add or modify this data.

Examples of database applications include:

Computerized  
library systems

Automated teller  
machines

Flight  
reservation  
systems

Computerized  
parts inventory  
systems

# Database Management System (DBMS) 2-3

A DBMS is a collection of related records and a set of programs that access and manipulate these records and enables the user to enter, store, and manage data.

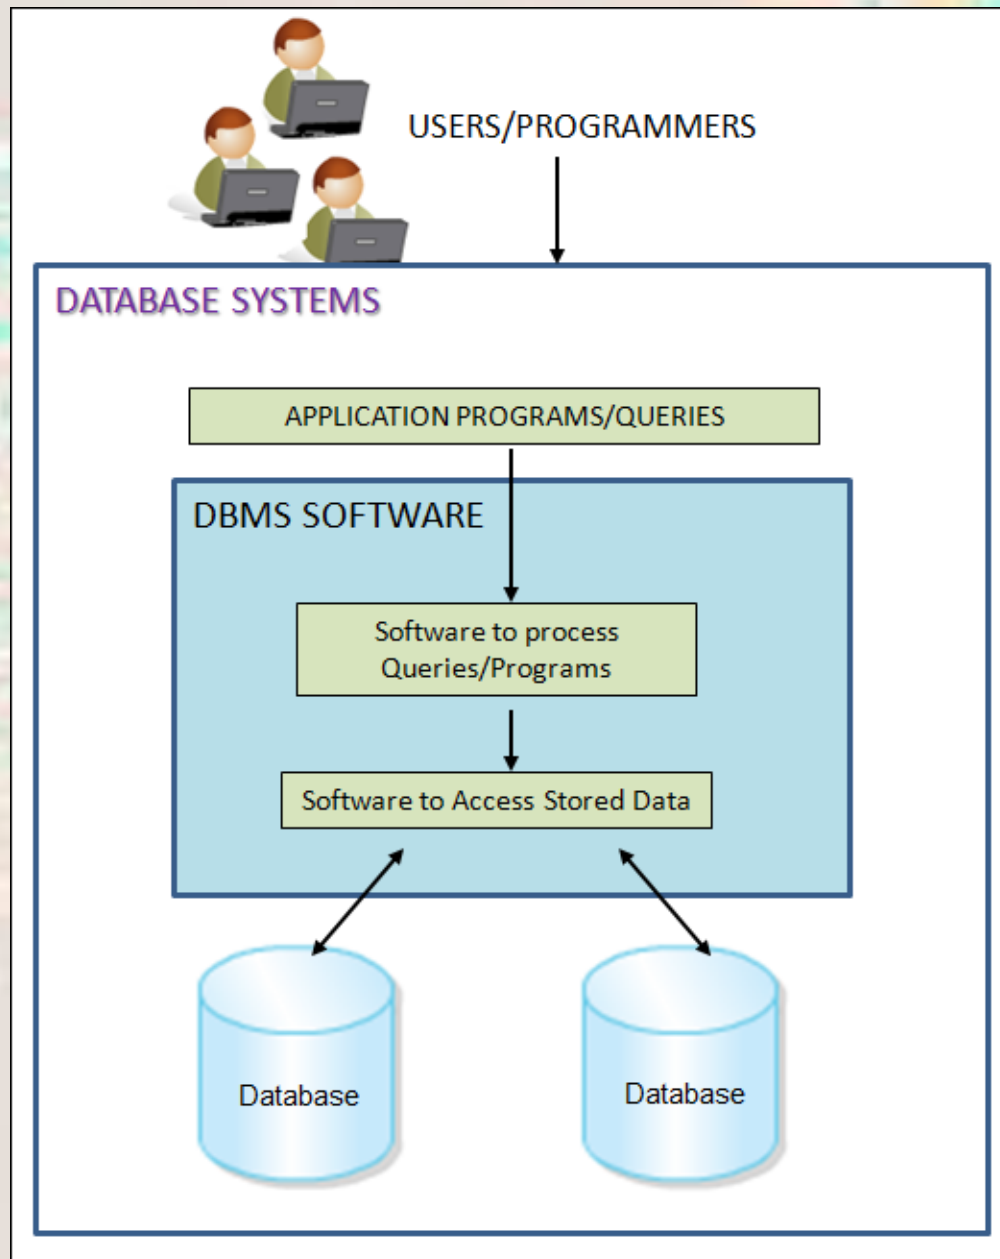

Example

In a centralized database system, the database is stored in the central location which everybody can have access from their machine.

A database is a collection of interrelated data and a DBMS is a set of programs used to add or modify this data.

# Database Management System (DBMS) 3-3

# Benefits of DBMS 1-2

A DBMS is responsible for processing data and converting it into information.

A database for this purpose has to be manipulated, which includes querying the database to retrieve specific data, updating the database, and finally, generating reports.

These reports are the source of information, which is, processed data.

A DBMS is also responsible for data security and integrity.

# Benefits of DBMS 2-2

Data storage

Data definition

Data manipulation

Data security and integrity

Data recovery and concurrency

Performance optimization

Multi-user access control

Database access languages and Application Programming Interfaces (APIs)

# Database Models

Databases can be differentiated based on functions and model of the data.

A data model describes a container for storing data, and the process of storing and retrieving data from that container.

Analysis and design of data models has been the basis of the evolution of databases.

Each model has evolved from the previous one.

Commonly used Database Models are:

**Flat-file Data Model**

**Hierarchical Data Model**

**Network Data Model**

**Relational Data Model**

# Flat-file Data Model

In this model, the database consists of only one table or file

Is used for simple databases - for example, to store the roll numbers, names, subjects, and marks of a group of students

Cannot handle very complex data. It can cause redundancy when data is repeated more than once

➤ Following table depicts structure of a flat file database:

Roll Number	First Name	Last Name	Subject	Marks
45	Jones	Bill	Maths	84
45	Jones	Bill	Science	75
50	Mary	Mathew	Science	80

# Hierarchical Data Model 1-3

In this model:

Different records are inter-related through hierarchical or tree-like structures.

Relationships are thought of in terms of children and parents.

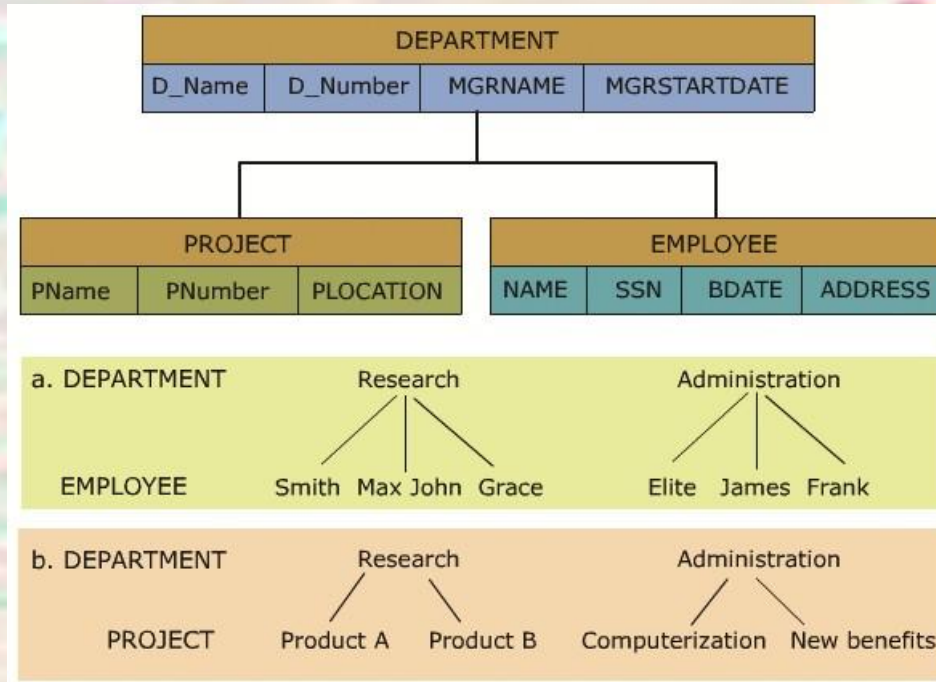

A parent record can have several children, but a child can have only one parent.

To find data stored in this model, the user needs to know the structure of the tree.

Windows Registry is an example of a hierarchical database storing configuration settings and options on Microsoft Windows operating systems.

# Hierarchical Data Model 2-3

- Following figure illustrates an example of a hierarchical representation:

- Within the hierarchical model, **Department** is perceived as the parent of the segment.
- The tables, **Project** and **Employee**, are children.
- A path that traces the parent segments beginning from the left, defines the tree.
- This ordered sequencing of segments tracing the hierarchical structure is called the hierarchical path.

# Hierarchical Data Model 3-3

- Advantages of a hierarchical model are as follows:

Data is held in a common database so data sharing becomes easier, and security is provided and enforced by a DBMS.

Data independence is provided by a DBMS, which reduces the effort and costs in maintaining the program.

This model is very efficient when a database contains a large volume of data.

- For example, a bank's customer account system fits the hierarchical model well because each customer's account is subject to a number of transactions.

# Network Data Model 1-4

This model is similar to the Hierarchical Data Model. It is actually a subset of the network model.

In the network data model, data is stored in sets, instead of the hierarchical tree format. This solves the problem of data redundancy.

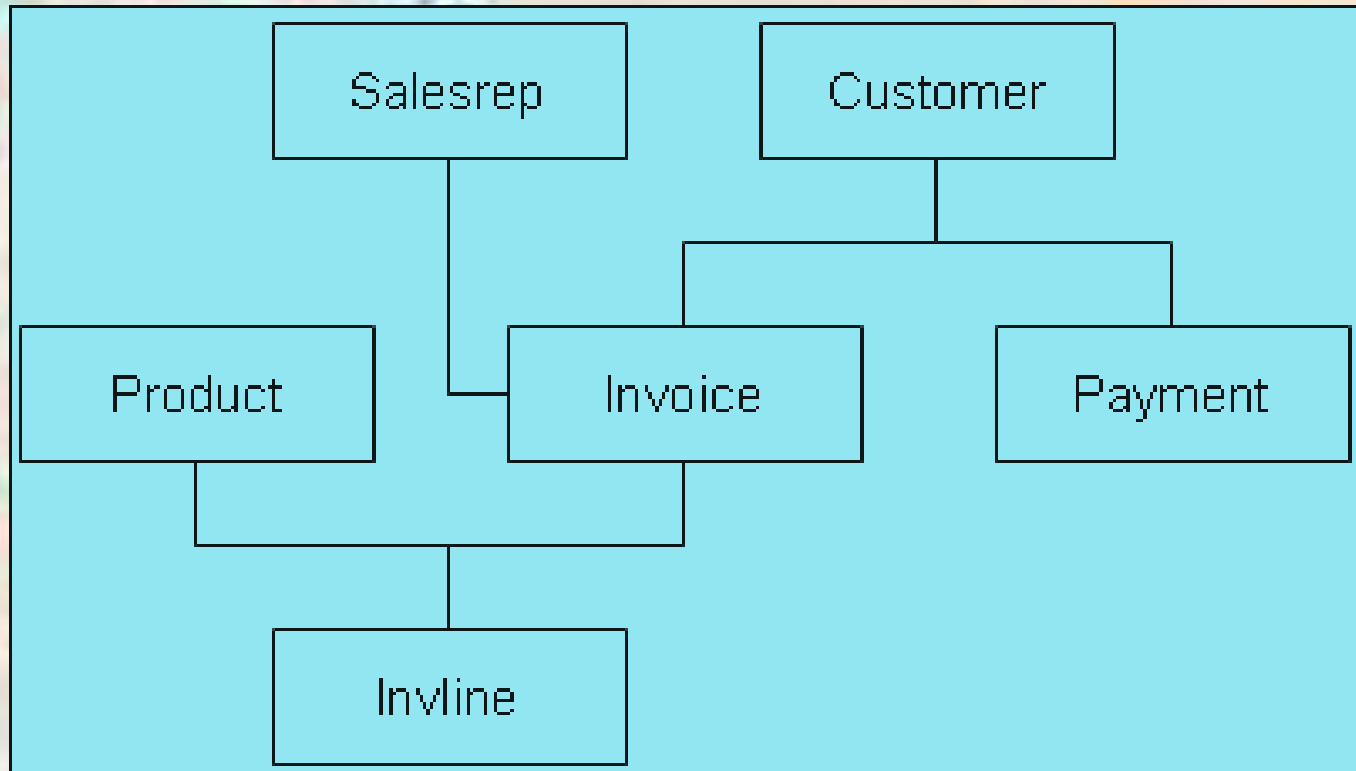

For every database, a definition of the database name, record type for each record, and the components that make up those records is stored. This is called its network schema.

It allows application programs to access the required data from the database. Raima Database Manager (RDM) Server by Raima Inc. is an example of a Network DBMS.

# Network Data Model 2-4

- Figure illustrates a series of one-to-many relationships:

# Network Data Model 3-4

- Components of the language used with network models are:

## Data Definition Language (DDL)

- Used to create and remove databases and database objects. It enables the database administrator to define the schema components.

## Sub schema DDL

- Enables the database administrator to define database components.

## Data Manipulation Language (DML)

- Used to insert, retrieve, and modify database information.

## Data Control Language (DCL)

- Used to administer permissions on the databases and database objects.

# Network Data Model 4-4

## ➤ Advantages are:

Relationships are easier to implement in the network database model than in the hierarchical model.

This model enforces database integrity.

This model achieves sufficient data independence.

## ➤ Disadvantages are:

The databases in this model are difficult to design.

The programmer has to be familiar with the internal structures to access the database.

The model provides a navigational data access environment.

- This model is difficult to implement and maintain.
- Computer programmers, rather than end users, utilize this model.

# Relational Data Model 1-5

As the information needs grew and more sophisticated databases and applications were required, database design, management, and use became too cumbersome.

This led to the development of what came to be called the Relational Model database.

The term 'Relation' is derived from the set theory of mathematics. In the Relational Model, unlike the Hierarchical and Network models, there are no physical links.

All data is maintained in the form of tables consisting of rows and columns. Data in two tables is related through common columns and not physical links.

Operators are provided for operating on rows in tables. This model represents the database as a collection of relations.

# Relational Data Model 2-5

A row is called a tuple, a column, an attribute, and the table is called a relation.

The list of values applicable to a particular field is called domain.

Several attributes can belong to the same domain.

The number of attributes of a relation is called degree of the relation.

The number of tuples determines the cardinality of the relation.

# Relational Data Model 3-5

- In order to understand the relational model, consider **Students** and **Marks** tables:

Roll Number	Student Name
1	Sam Reiner
2	John Parkinson
3	Jenny Smith
4	Lisa Hayes
5	Penny Walker
6	Peter Jordan
7	Joe Wong

Students Table

Roll Number	Marks Obtained
1	34
2	87
3	45
4	90
5	36
6	65
7	89

Marks Table

- **Students** table displays the **Roll Number** and the **Student Name** and the **Marks** table displays the **Roll Number** and **Marks** obtained by the students.
- To locate students with marks above 40:
- First, locate the roll numbers of those who have scored above 50 from the **Marks** table.
  - Second, their names have to be located in the **Students** table by matching the roll number.

# Relational Data Model 4-5

- The result is displayed as shown in the following table:

Roll Number	Student Name	Marks Obtained
2	John	87
4	Lisa	90
6	Peter	65
7	Joe	89

- It was possible to get this information because of two facts:

First, there is a column common to both the tables - **Roll Number**.

Second, based on this column, the records from two different tables could be matched and the required information could be obtained.

- In a relational model, data is stored in tables.
- A table in a database has a unique name that identifies its contents.
- Each table can be defined as an intersection of rows and columns.

# Relational Data Model 5-5

## Advantages of the relational model

Gives programmer time to concentrate on logical view of the database rather than being bothered about the physical view.

Provides querying flexibility and hence, leads to popularity of relational databases.

Easy to handle model to the extent that even untrained people find it easy to generate handy reports and queries, without giving much thought to the need to design a proper database.

## Disadvantages of the relational model

Hides all complexities of the system and hence, it tends to be slower than other database systems.

# Relational Database Management System (RDBMS) 1-3

Relational Model is an attempt to simplify database structures.

Represents all data in the database as simple row-column tables of data values.

An RDBMS is a software program that helps to create, maintain, and manipulate a relational database.

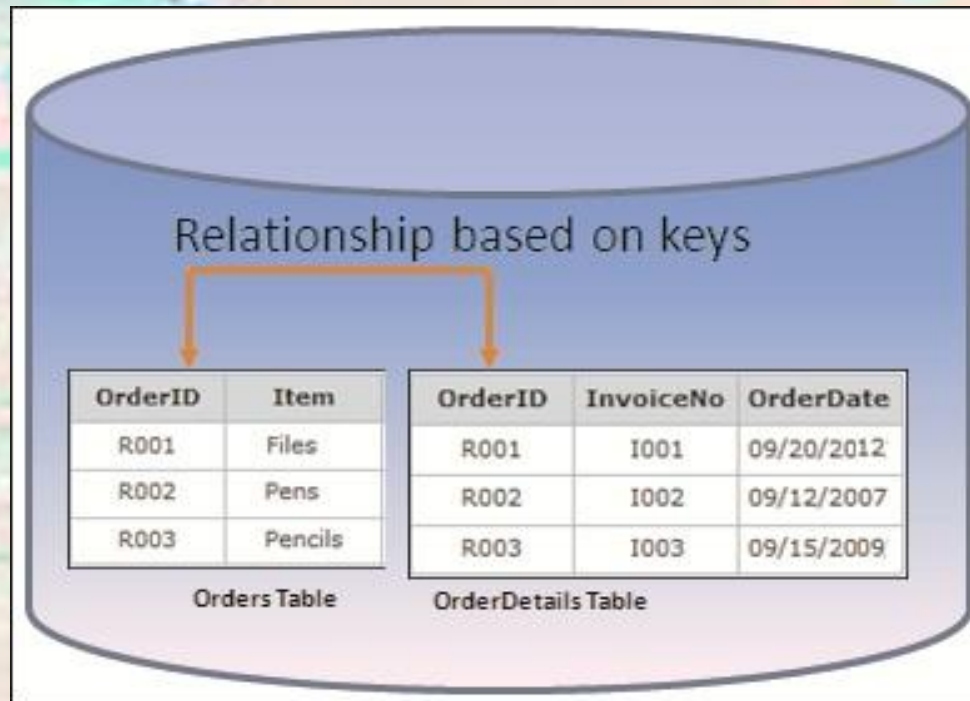

A relational database is a database divided into logical units called tables, where tables are related to one another within the database.

By having common keys, or fields, among relational database tables, data from multiple tables can be joined to form one large resultset.

# Relational Database Management System (RDBMS) 2-3

- Figure shows two tables related to one another through a common key (data value) in a relational database:

- Thus, a relational database is a database structured on the relational model.
- Basic characteristic of a relational model is that in a relational model, data is stored in relations.

# Relational Database Management System (RDBMS) 3-3

- **Capitals** and **Currency** tables show a list of countries and their capitals and the countries and the local currencies used by them respectively:

Country	Capital
Greece	Athens
Italy	Rome
USA	Washington
China	Beijing
Japan	Tokyo
Australia	Sydney
France	Paris

Capitals Table

Country	Currency
Greece	Drachma
Italy	Lira
USA	Dollar
China	Renminbi (Yuan)
Japan	Yen
Australia	Australian Dollar
France	Francs

Currency Table

- Both tables have a common column, that is, the **Country** column.
- Now, to display the information about the currency used in Rome, first find the name of the country to which Rome belongs from table **Capitals**.
- Next, that country should be looked up in table **Currency** to find out the currency.
- It is possible to get this information because it is possible to establish a relation between the two tables through a common column called **Country**.

# Terms Related to RDBMS 1-3

- Terms that are mostly used in an RDBMS are described as follows:

Data is presented as a collection of relations.

Each relation is depicted as a table.

Columns are attributes.

Rows ('tuples') represent entities.

Every table has a set of attributes that are taken together as a 'key' (technically, a 'superkey'), which uniquely identifies each entity.

# Terms Related to RDBMS 2-3

- Consider the scenario of a company maintaining customer and order information for products being sold and customer-order details for a specific month, say, August.
- Following tables are used to illustrate this scenario:

Cust_No	Cust_Name	Phone No
002	David Gordon	0231-5466356
003	Prince Fernandes	0221-5762382
003	Charles Yale	0321-8734723
002	Ryan Ford	0241-2343444
005	Bruce Smith	0241-8472198

Customer

Item_No	Description	Price
HW1	Power Supply	4000
HW2	Keyboard	2000
HW3	Mouse	800
SW1	Office Suite	15000
SW2	Payroll Software	8000

Items

Ord_No	Item_No	Qty
101	HW3	50
101	SW1	150
102	HW2	10
103	HW3	50
104	HW2	25
104	HW3	100
105	SW1	100

Order\_Details

Ord_No	Ord_Date	Cust_No
101	02-08-12	002
102	11-08-12	003
103	21-08-12	003
104	28-08-12	002
105	30-08-12	005

Order\_August

# Terms Related to RDBMS 3-3

- Following table lists terms related to tables:

Term	Meaning	Example from the Scenario
Relation	A table	Order_August, Order_Details, Customer and Items
Tuple	A row or a record in a relation	A row from Customer relation is a Customer tuple
Attribute	A field or a column in a relation	Ord_Date, Item_No, Cust_Name, and so on
Cardinality of a relation	The number of tuples in a relation	Cardinality of Order_Details relation is 7
Degree of a relation	The number of attributes in a relation	Degree of Customer relation is 3
Domain of an attribute	The set of all values that can be taken by the attribute	Domain of Qty in Order_Details is the set of all values which can represent quantity of an ordered item
Primary Key of a relation	An attribute or a combination of attributes that uniquely defines each tuple in a relation	Primary Key of Customer relation is Cust_No  Ord_No and Item_No combination forms the primary key of Order_Details
Foreign Key	An attribute or a combination of attributes in one relation R1 that indicates the relationship of R1 with another relation R2.  The foreign key attributes in R1 must contain values matching with those of the values in R2	Cust_No in Order_August relation is a foreign key creating reference from Order_August to Customer. This is required to indicate the relationship between orders in Order_August and Customer

# RDBMS Users 1-2

- Many persons are involved in the design, use, and maintenance of a large database with a few hundred users.

## Database Administrator (DBA)

- Collects information that will be stored in the database
- Responsible for authorizing access to database
- Coordinating and monitoring its use
- Acquiring software and hardware resources as needed
- Accountable for problems such as breach of security or poor system response time

## Database Designer

- Responsible for identifying the data to be stored in the database
- Choosing appropriate structures to represent and store this data
- Communicate with all prospective database users, in order to understand their requirements
- To come up with a design that meets the requirements

# RDBMS Users 2-2

## System Analysts and Application Programmers

- Determine the requirements of end users
- Develop specifications for pre-determined transactions that meet these requirements
- Implement these specifications as programs
- Test, debug, document, and maintain these pre-determined transactions
- Design, development, and operation of the DBMS software and system environment

## DBMS Designers and Implementers

- Design and implement the DBMS modules and interfaces as a software package.

## End User

- The end user invokes an application to interact with the system, or writes a query for easy retrieval, modification, or deletion of data.

# Entity

An entity is a person, place, thing, object, event, or even a concept, which can be distinctly identified.

Each entity has certain characteristics known as attributes.

A grouping of related entities becomes an entity set. Each entity set is given a name. The name of the entity set reflects the contents.

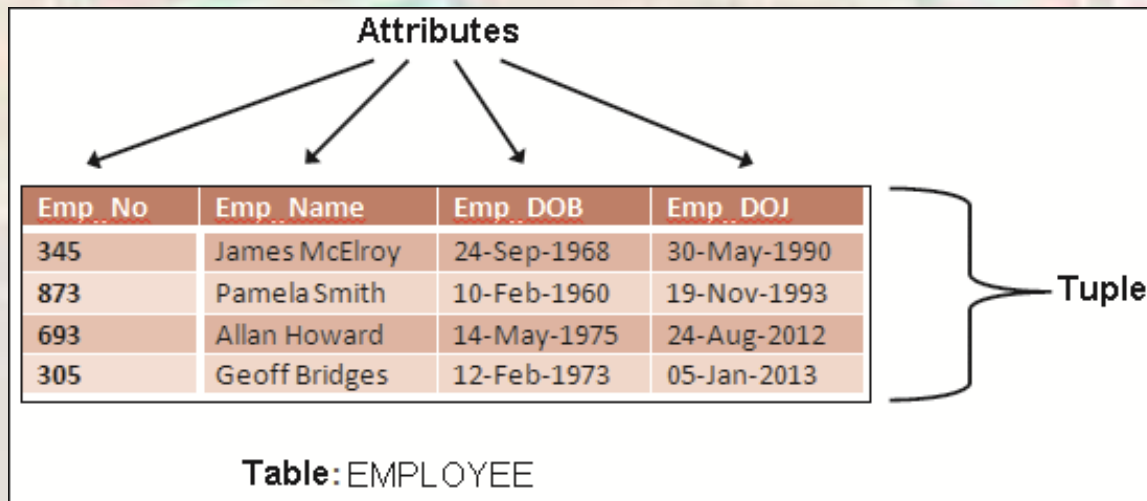

# Tables and their Characteristics 1-2

Access and manipulation of data is facilitated by creation of data relationships based on a construct known as a table.

A table contains a group of related entities that is an entity set. The terms entity set and table are often used interchangeably.

A table is also called a relation. The rows are known as tuples. The columns are known as attributes.

➤ Following figure highlights characteristics of a table:

# Tables and their Characteristics 2-2

## ➤ Characteristics of a table:

A two-dimensional structure composed of rows and columns is perceived as a table.

Each tuple represents a single entity within the entity set.

Each column has a distinct name.

Each row/column intersection represents a single data value.

Each table must have a key known as primary key that uniquely identifies each row.

All values in a column must conform to the same data format.

Each column has a specific range of values known as the attribute domain.

Each row carries information describing one entity occurrence.

The order of the rows and columns is immaterial in a DBMS.

# Differences between a DBMS and an RDBMS

DBMS	RDBMS
It does not need to have data in tabular structure nor does it enforce tabular relationships between data items.	In an RDBMS, tabular structure is a must and table relationships are enforced by the system. These relationships enable the user to apply and manage business rules with minimal coding.
Small amount of data can be stored and retrieved.	An RDBMS can store and retrieve large amount of data.
A DBMS is less secure than an RDBMS.	An RDBMS is more secure than a DBMS.
It is a single user system.	It is a multiuser system.
Most DBMSs do not support client/server architecture.	It supports client/server architecture.
Here, entities are given more importance and there is no relation established among these entities.	Here, a relation is given more importance. Thus, the tables in an RDBMS are dependent and the user can establish various integrity constraints on these tables so that the ultimate data used by the user remains correct.

# Summary

- A database is a collection of related data stored in the form of a table.
- A data model describes a container for storing data and the process of storing and retrieving data from that container.
- A DBMS is a collection of programs that enables the user to store, modify, and extract information from a database.
- A Relational Database Management System (RDBMS) is a suite of software programs for creating, maintaining, modifying, and manipulating a relational database.
- A relational database is divided into logical units called tables. These logical units are interrelated to each other within the database.
- The main components of an RDBMS are entities and tables.
- In an RDBMS, a relation is given more importance, whereas, in case of a DBMS, entities are given more importance and there is no relation established among these entities.
